Chapter 1 Introduction

1.1 Overview

The RK816 is a complex power management integrated circuit (PMIC) for multi-core system applications powered by Li-ion polymer battery cell, or by a 5V input either form an USB port or form an adapter. The RK816 can provide a complete power management solution with very few external components.

The RK816 provides four configurable synchronous step-down converters, and six LDO regulators. The device also contains a bi-directional charger, the power path management function, and a battery fuel gauge. Power up/power down controller is configurable and can support any customized power up/power down sequences (OTP based). A real time clock (RTC) is also integrated to provide a 32KHz output buffer, and real time function. The RK816 supports 32KHz clock generation based on a crystal oscillator.

The switch mode bi-directional charger, together with power path controller integrated in RK816, allows supplying power form the USB to the loads while it is charging the battery. The charger provides functions such as input current limiting, input voltage limiting, constant temperature charging, trickle current charging, constant current/constant voltage charging, charging termination, dead battery charging, charging over time protection, charging over or under temperature protection, etc. All these functions can be conveniently configured through the I2C digital interface. When the RK816 is powered only by the battery, the bi-directional charger can work on boost mode, it achieves OTG function by supplying power from the battery to the USB.

The charger input current limiting can be set to maximum 2A to accommodate a power adapter as the input supply. When the input current limiting is triggered, the power path controller will distribute the input power in a way that loads have the higher priority than the battery to take the input power. The difference between the input and output power will be used to charge the battery. In a case that the output power required by the loads exceeds the input power, the power path controller will automatically turn on the battery switch so that the battery can supply extra power to the loads together with input supply.

A battery fuel gauge is also integrated in the RK816. Using the proprietary algorithms and the sensed battery current and voltage, the gauge can accurately calculate the battery capacity based on the charging or discharging characteristics of the battery preloaded in the system. The gauge then sends the battery capacity information to the processor through the I2C interface.

The RK816 can dynamically adjust the output voltage of each DC-DC converter, as required by the processor based on the processor's operation status so as to maximize the system efficiency. The output voltages of most channels can be configured through I2C interface. The inputs of all channels have soft start function, which greatly reduces the inrush current at the start up. The frequency compensations of all the control loops are implemented internally to eliminate external compensation components. The 2MHz switching frequency allows small size inductors to be used for buck converters. Also, as all the power switches are integrated on chip, no external power switches and schottky diodes are needed, which reduces the system cost significantly.

The RK816 is available in a QFN40 5mmx5mm package, with a 0.40mm pin pitch.

Chapter 4 Function Description

4.1 Function overview

4.1.1 POWER UP/POWER DOWN

The RK816 can be powered by either a battery, or an external power supply through the USB port. When the PMIC is powered by battery only, pressing the PWRON key powers up the PMIC. All the power channels start up at the default output voltages with a press power up sequence, which has 2mS intervals between the channels. When the power up process is done, the NRESPWRON turns to high logic level to inform the processor that all the power rails are up and stable. And now the processor can communicate with the PMIC to re-configure the output voltage of each power channel if needed.

To power down the PMIC, the processor needs to issue a "power down" signal through the I2C interface. Upon receiving the power down signal, the PMIC first saves all the information on the existing states, and then switches the NRESPWRON to low logic level. At this point, the power channels start to be turned off one after another with the power done sequence. If for any reason the processor fails to issue the power down signal, the PMIC can be powered off by "pressing and holding" the PWRON key.

In a case where a battery is the sole power supply and the PMIC is in off state, when an external power supply is plugged into the USB, the PMIC will first check to see if this is a valid power supply. If the power supply from USB is valid, then the power channels are turned on and the battery is charged.

4.1.2 BI-DIRECTIONAL CHARGER

The RK816 has integrated a switch mode bi-directional charger, which provides the functions such as input current limiting, input voltage limiting, constant temperature charging, trickle current charging, constant current/constant voltage charging, charging termination, dead battery charging, charging over time protection, charging over or under temperature protection, etc. All these functions can be conveniently configured through the I2C digital interface.

The input average current limit function allows as large as possible a charging current to be used without having to worry about the input current exceeding the maximum current allowed by the USB port. The input current limits can be configured through I2C interface. For example, when an USB port is used as the input, the input current limit can be configured to either 450mA, or 820mA, to meet the requirements of USB2.0 and USB3.0 respectively.

The charger also has a timer function which sets the maximum charging time for trickle, constant current and constant voltage charging, respectively. If the charging does not complete when a preset maximum charging time is reached, the charging is terminated.

The battery temperature can be monitored through the TS pin. A battery typically has a thermistor inside. The RK816 sources a constant current into the thermistor and senses the voltage across the thermistor through an internal ADC. A safe charging temperature range is preset in the PMIC. The charging can proceed normally if the battery temperature falls within the preset range. If, however, the battery temperature goes either above the upper limit or below the lower limit of the preset range, the charging will pause until the battery temperature goes back in the preset range. If the value of the available thermistor is either too large or too small, a normal resistor can be connected in series or in parallel with the thermistor so that the sensed voltage fits the ADC's input range.

During Charging, Vsys will be set to 3.6V when the battery voltage is below 3.6V. This design is to guarantee that when an external power supply is plugged into the USB port to charge the battery while the battery voltage is low, the Vsys is already at 3.6V, which allows the PMIC to start up quickly without having to wait for the Vsys ramping up.

4.1.3 BOOST AND OTG

When the RK816 is powered only by the battery, the bi-directional charger can work on boost mode, it achieve OTG function by supplying power from the battery to the USB. The synchronous boost converter has 0.8A current capability and is used to power the OTG. The OTG has a built-in current limiting switch, which can effectively protect the boost converter from being damaged if a short circuit occurs at the OTG port.

As the USB input port and the OTG output port share a same pin, when the USB port is being used as a power supply and charging the battery, the OTG switch is forbidden to be turned on. Only when there is no external power supply plugged into the USB port, can the OTG be turned on and serve as a power supply.

The key parameters such as output voltage, and output current limit can be configured through the I2C interface.

4.1.4 POWER PATH MANAGEMENT

A power path management function is integrated in the RK816, which together with the accurate input current limit function, can provide intelligent power path control. In a power path control process, the PMIC gives the outputs, or the system loads, the highest priority of using the input power. The battery is getting charged only if the input power is greater than the output power required by the system loads. The intelligent power path control function automatically reduces the charging current when the output power required by the loads increases. In an extreme case where the required output power is greater than the input power, the charging current will be cut off and the battery will join the input power supply to provide power to the load. This is how the intelligent power path control works: As the system power loading increases, the PMIC will draw more input current from the power supply to meet the output power requirement while keep the charging current unchanged. If the system power loading continues to increase to the point where the input current limit is reached, then the PMIC will lower the charging current so that enough power still goes to the load. If the system power loading further increases and due to the input current limit, the input power can't meet the output power requirement, then the battery will start to discharge to supply power to the load together with the USB power supply. If for some reason the USB is unplugged, the battery will automatically switched in to take over the USB power supply and provide full power to the load. The wide power path loop bandwidth allows all the above mentioned power path switching transient to be quick and seamless and therefore no overshoot and notch occur at the system and output voltages.

To minimize the loss from the voltage drop along the current path when the battery is charged or discharged, an 80mΩ MOSFET is integrated in the RK816 to serve as a control switch as well as the power switch of the switching mode battery charger.

4.1.5 BATTERY FUEL GAUGE

The RK818 provides an accurate battery fuel gauge. A 12-bit ADC is integrated in the RK816 to collect the information on the battery, such as battery voltage, USB voltage, charging/discharging status, battery temperature, etc. Using the proprietary algorithms and the information collected by the ADC, the battery fuel gauge can accurately calculate the battery capacity based on the charging/discharging characteristics of the battery preloaded in the system. The gauge then sends the battery capacity information to the processor through the I2C interface.

4.1.6 BUCK CONVERTERS

The RK816 provides four high current synchronous buck converters, which deliver up to 2A, 2A, 1A and 1A, respectively. An enhanced current mode architecture is used, which improves the transient response significantly. All output voltages can be adjusted dynamically during operation through DVS (Dynamic Voltage Scaling), which guarantees a linear and gradual voltage ramping up and down. A complete set of protection functions, such as short circuit protection, is implemented in the buck converters too.

The inputs of all channels have soft start function, which greatly reduces the inrush current at the start up. The frequency compensations of all the control loops are implemented internally to eliminate external compensation components. The 2MHz switching frequency

allows small size inductors to be used for buck converters. Also, as all the power switches are integrated on chip, no external power switches and schottky diodes are needed, which reduces the system cost significantly.

4.1.7 LOW DROPOUT REGULATORS

The RK816 also integrates six LDOs, with five LDOs (LDO1, LDO2, LDO4, LDO5 and LDO6) capable of providing up to 300mA and one LDOs (LDO3) providing maximum 100mA. The LDO3 is a low noise, high PSRR LDO which delivers up to 100mA current. The parameters such as output voltage in the different operating modes can be adjusted through the I2C interface.

4.1.8 REAL TIME CLOCK

The RK816 integrates a crystal oscillator buffer and a real time clock (RTC). The buffer works with an external 32.768kHz crystal oscillator. With the RTC function, the PMIC provides second/minute/hour/day/month/year information, alarm wake up as well as time calibration. The RK816 provides one channel of 32.768kHz clock with open drain outputs, which is enabled through I2C interface.

4.3 Device Power on Enable Conditions

If none of the device power-on disable conditions is met, the following conditions are available to turn on and/or maintain the ON state of the device:

- PWRON signal is low for a period of time
- USB is plugged in.（PLUG_IN_INT goes to high level）
- RTC set time power on

4.4 Device Power on Disable Conditions

The PMIC will be powered off, or can not be powered on under the following conditions:

- PWRON signal keeps at low lever longer than the long-press delay TDPWRONLP and PWRON_LP_ACT is set to "0"（If it is set to "1", the PMIC will restart automatically after the it is shut down ）The interrupt corresponding to this condition is PWRON_LP_INT in the INT_STS_REG register.
- The die temperature reaches the TSD threshold, in which case the TSD_STS bit in the register THERMAL_REG is set to "1".
- Vsys is lower than UVLO threshold, in which case the VB_UV_STS bit in the register

VB_MON_REG is set to "1".
- Vsys is lower than the low voltage warning threshold which can be set with the VB_LO_SEL bit in the register VB_MON_REG, and the VB_LO_ACT bit is set to "0".
- Vsys is higher than the over voltage protection threshold.
- The DEV_OFF control bit is set to "1". (DEV_OFF is reset when the system is powered off).

4.5 Device Sleep Enable Conditions

Chapter 6 Thermal Management

6.1 Overview

For reliability and operability concerns, the absolute maximum junction temperature of RK816 has to be below 125ºC.

Depending on the thermal mechanical design (Smartphone, Tablet, Personal Navigation Device, etc), the system thermal management software and worst case thermal applications, the junction temperature might be exposed to higher values than those specified above.

Therefore, it is recommended to perform thermal simulations at device level (Smartphone, Tablet, Personal Navigation Device, etc) with the measured power of the worst case UC of the device.

6.2 Package Thermal Characteristics

Table 6-1 provides the thermal resistance characteristics for the package used on this device.

Table 6-1 Thermal Resistance Characteristics

PACKAGE (QFN5X5-40)	**POWER(W)**	$\boldsymbol{\theta_{JA}}(℃/\boldsymbol{W})$	$\boldsymbol{\theta_{JB}}(℃/\boldsymbol{W})$	$\boldsymbol{\theta_{JC}}(℃/\boldsymbol{W})$
RK816	2	36	17	2.3

Note: The testing PCB is based on 4 layers, 114mm x 76 mm, 1.6mm thickness, Ambient temperature is 85°C.
